PROBLEM STATEMENT

- Manual entry of User details (Name, address, mobile, e-mail) are required to be entered on different sites repetitively, with each detail being filled separately.

- If any detail about the user is changed, commonly their address, they need to visit each of these services (Amazon, flipkart, zomato) and change their details on each service/site repetitively & redundantly.

Proposed Solution

- In order to abolish users' repetitive need to update their information on each platform, a unique code mapped to each user's details will be generated.

- This unique code/pin/phrase stores the user details on a secure database, and is shared/provided to the platform/service upon authorization by user.

Future Scope

- Since the user data can be accessed from the unique code, the user will also have the right to remove the information access from any platform they seem fit and grant the access back within a time period

- This will be similar to Aadhar authentication, but for most common user details, all centralized in one place.

Thank You
